The General Motors EMD engine line is typical of the two-stroke diesel breed. These engines were introduced in the 1930s and power a large number of the diesel locomotives found in the United States. There have been three successive series in the EMD line: the 567 series, the 645 series, and the 710 series. The numbers refer to the number of cubic inches per cylinder, with a typical engine having 16 cylinders (for a total displacement on the order of 10,000 cubic inches!).

A diesel locomotive is a type of railway locomotive in which the prime mover is a diesel engine. Several types of diesel locomotives have been developed, differing mainly in the means by which mechanical power is conveyed to the driving wheels. Early internal combustion locomotives and railcars used kerosene and gasoline as their fuel.

The GE (General Electric) 7FDL is a series of four-stroke prime-movers or diesel engine (motor) models built by GE from 1956 to 2004, but is still in production for export models. They consist of 8, 12, and 16 cylinder configurations, and are typically arranged in a "V" formation like many other prime-movers built for diesel locomotives (such as the EMD 567). First designed by Cooper-Bessemer ...

The difference between diesel and electric locomotives is that the diesel engine carries its own power plant, which is the diesel prime mover, instead of being connected from the overhead wires. Diesel-electric locomotives usually have two different types of electric current, AC and DC. AC current provides improved traction over DC locomotives.

It seems that by the 1977-1978 general date of the Conrail manual that is our primary source, these were production standard for all FDL engines in 8, 12 and 16 cylinders. Also at this time all FDL engines were changed to a fuel header pressure of 39-41 psi. These used the same (large) fuel pump system as previously employed.
